

5-Minute Presentation Script

Secure Access, WAN Connectivity & Cloud Security Controls

CompTIA Security+ SY0-701 | Lesson 187.6 | Team 6

[0:00 – 0:45] — Opening & Cloud Data Protection

Speaker A:

"Hey everyone — today we're talking about something that's become critical in modern IT: how do we keep data secure when our workforce is fully remote and everything lives in the cloud?"

Let's start with **cloud data protection**. Think about a company like Zoom or Salesforce — they run on AWS or Azure. The cloud provider secures the *physical infrastructure* — the servers, data centers, the network. But here's the key: **you**, as the customer, are responsible for encrypting your data, managing encryption keys, configuring DLP — Data Loss Prevention — and controlling access.

Real-world example: In **2019, Capital One had a massive breach on AWS**. AWS's infrastructure was totally fine — the problem was a misconfigured firewall *the customer controlled*. That's the **shared responsibility model** in action."

[0:45 – 1:45] — SD-WAN

Speaker B:

"Great point. Now let's talk about how traffic gets from point A to point B securely — that's where **SD-WAN** comes in.

SD-WAN stands for **Software-Defined Wide Area Network**. Traditionally, companies paid for expensive dedicated MPLS circuits — think of it like leasing a private highway just for your company's traffic. SD-WAN replaces that with **encrypted tunnels over**

regular internet connections — much cheaper and way more flexible.

It runs on three planes: the **control plane** makes routing decisions, the **data plane** moves traffic and enforces security policies, and the **management plane** monitors everything.

Real-world example: **Target** has hundreds of retail locations. Instead of paying for dedicated MPLS lines to every store, SD-WAN lets them route traffic over broadband with centralized policy management — cutting costs while keeping security consistent across every branch."

[1:45 – 3:15] — SASE Architecture

Speaker A:

"Now here's where it gets really interesting — **SASE**, pronounced 'sassy' — Secure Access Service Edge.

SASE takes SD-WAN and bundles it with a full cloud-delivered security stack: **ZTNA** — Zero Trust Network Access, **SWG** — Secure Web Gateway, **CASB** — Cloud Access Security Broker, and **FWaaS** — Firewall as a Service. All from the cloud.

Here's the scenario that makes this click: Imagine **Sarah**, a remote worker in Chicago, trying to access Salesforce. With a traditional VPN, her traffic goes: *Chicago → VPN tunnel → Corporate HQ in New York → Internet → Salesforce*.

That's **backhauling** — slow, expensive, and a bottleneck."

Speaker B:

"Right — and with SASE, that same traffic goes: *Chicago → Nearest SASE Point of Presence (PoP) → Salesforce*.

At that PoP, ZTNA verifies Sarah's identity — *never trust, always verify* — the SWG scans for malware and phishing, CASB ensures she's not leaking data to an unauthorized app, and FWaaS applies firewall rules. All at the cloud edge, closest to where Sarah actually is.

Real companies doing this? **Cisco Umbrella** and **Palo Alto Prisma Access** are both SASE platforms used by enterprises worldwide."

[3:15 – 4:15] — Comparison & Exam Tip

Speaker A:

"Let's quickly compare the three models:

- **Traditional MPLS/VPN** — dedicated lines, perimeter firewall, implicit trust once inside. Expensive and rigid.
- **SD-WAN** — encrypted internet overlay, centralized policy, better performance. Still somewhat HQ-centric.
- **SASE** — fully cloud-delivered, built-in Zero Trust, subscription-based, no backhauling. Best fit for today's remote-first world.

For the exam: **SASE = SD-WAN + the full security stack, delivered as one cloud service.** And ZTNA is a *component* of SASE — not a replacement for it."

[4:15 – 5:00] — Practice Question & Wrap-Up

Speaker B:

"Let's close with an exam-style question:

A company's remote workers are complaining about slow performance when accessing SaaS apps through the corporate VPN. What should the security team deploy?

A) More VPN concentrators | **B)** SD-WAN at branches | **C)** SASE with cloud-delivered PoPs | **D)** Split tunneling

The answer is **C — SASE**. VPN concentrators and SD-WAN branches still backhaul traffic through HQ. Split tunneling speeds things up but *removes security inspection* — that's a hard no on the exam."

Speaker A:

"Exactly. The perimeter is dead — security now lives in the cloud. SASE is how modern organizations protect users wherever they are, without sacrificing performance.

Thanks for listening — we're happy to take any questions!"

Estimated Runtime: ~5 minutes | The real-world examples (Capital One, Target, Sarah's VPN scenario) are your best spots to slow down and let it land.
